Complex Analysis 1: Integration Essentials

A journey through the fundamental concepts of integration in the complex plane, exploring how analytic functions transform our understanding of calculus.

Cauchy-Riemann Equations and Analyticity Review

For a complex function $f(z) = u(x, y) + iv(x, y)$ to be analytic, it must satisfy the Cauchy-Riemann equations at every point:

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} \quad \text{and} \quad \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}$$

These elegant relationships connect the real and imaginary parts of the function, ensuring smooth behavior and differentiability in the complex plane.

Contour Integration: Defining the Path

Parameterized Curve

A contour γ is a piecewise-smooth path defined by $z(t) = x(t) + iy(t)$ for $t \in [a, b]$

Orientation Matters

The direction of traversal affects the integral's sign. Reversing the path multiplies the result by -1

Complex Integral

$\int_\gamma f(z)\,dz = \int_a^b f(z(t))z'(t)\,dt$

The Fundamental Theorem of Calculus for Complex Functions

When $f(z)$ is analytic with antiderivative $F(z)$, the complex version mirrors the real case beautifully:

1

Antiderivative Exists

$F'(z) = f(z)$ throughout the domain

2

Path Independence

The integral depends only on endpoints

3

Simple Formula

$\int_\gamma f(z)\,dz = F(b) - F(a)$

This powerful result means that for analytic functions, the path of integration becomes irrelevant–only the start and end points matter.

Cauchy's Integral Theorem: When Paths Don't Matter

If $f(z)$ is analytic inside and on a simple closed contour γ, then:

$$\oint_\gamma f(z)\,dz = 0$$

This remarkable theorem reveals that analytic functions are *conservative* in the complex plane. The total "work" around any closed loop vanishes, fundamentally distinguishing complex analysis from real calculus.

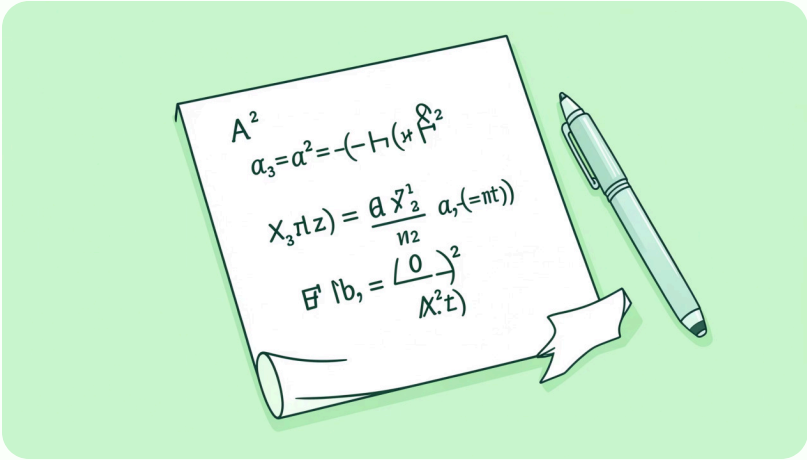
Cauchy's Integral Formula: Unlocking Function Values



For an analytic function $f(z)$ and a point z_0 inside contour γ:

$$f(z_0) = \frac{1}{2\pi i} \oint_\gamma \frac{f(z)}{z - z_0}\, dz$$

This formula is revolutionary–it expresses function values as contour integrals, connecting local behavior to global properties.

01

Function Value at Point

$f(z_0)$ is determined by integration around the contour

02

Kernel Function

The term $\frac{1}{z-z_0}$ acts as a weighting function

03

Global Information

Values on the entire contour influence the point evaluation

Derivatives of Analytic Functions: An Extension of Cauchy's Formula

Amazingly, Cauchy's formula extends to derivatives of all orders, revealing that analytic functions are infinitely differentiable:

$$f^{(n)}(z_0) = \frac{n!}{2\pi i} \oint_\gamma \frac{f(z)}{(z - z_0)^{n+1}}\, dz$$

n = 0: Original Formula

Recovers the standard Cauchy integral formula

n = 1: First Derivative

$f'(z_0) = \frac{1}{2\pi i} \oint \frac{f(z)}{(z-z_0)^2}\, dz$

n = 2: Second Derivative

$f''(z_0) = \frac{1}{\pi i} \oint \frac{f(z)}{(z-z_0)^3}\, dz$

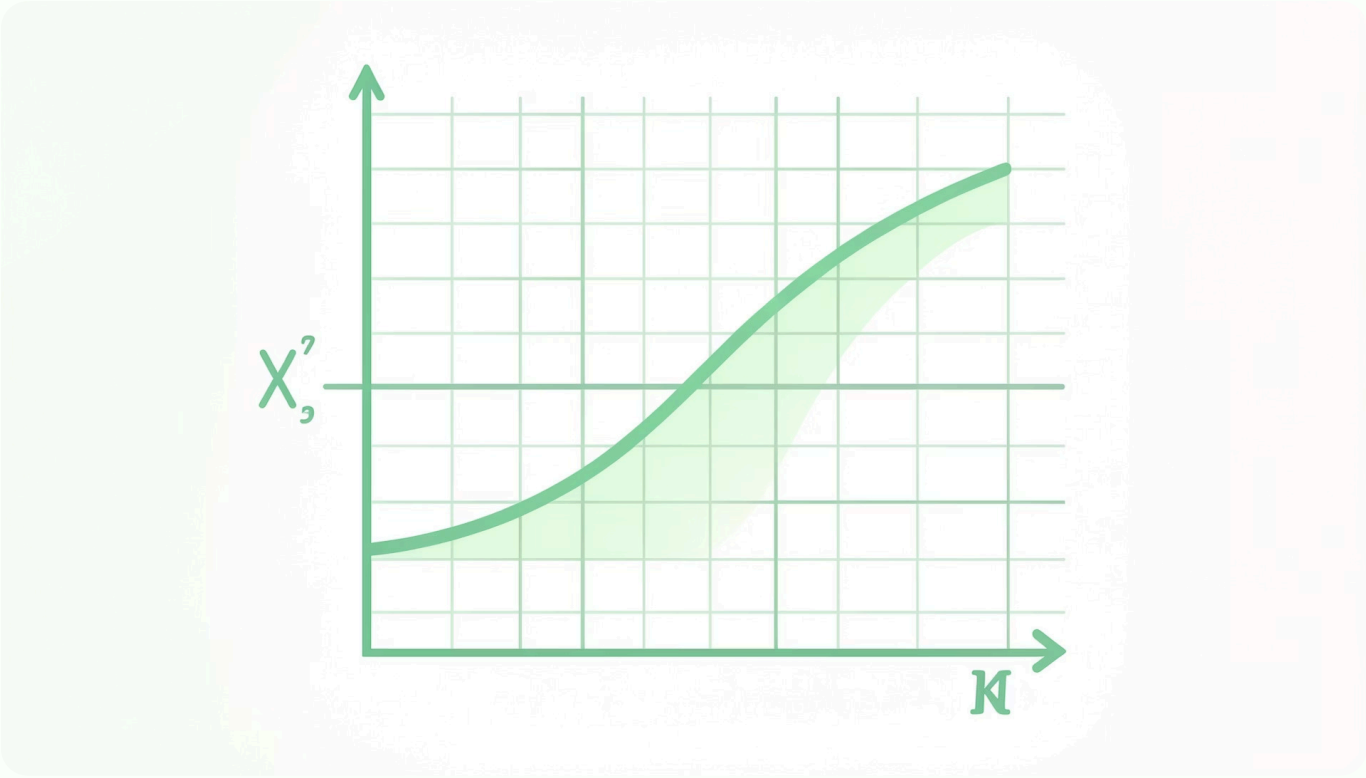
Liouville's Theorem and Entire Functions

The Statement

If a function $f(z)$ is analytic everywhere in $\mathbb{C}$ (entire) and bounded, then $f(z)$ must be constant.

This seemingly simple result has profound implications throughout mathematics and physics.



Bounded

$|f(z)| \leq M$ for all $z \in \mathbb{C}$

Entire

Analytic at every point in the complex plane

Constant

The only possibility under these conditions

The Maximum Modulus Principle: Bounding Our Functions

If $f(z)$ is analytic and non-constant in a domain D, then $|f(z)|$ cannot attain a maximum in the interior of D.

1 **Interior Points**

Maximum modulus occurs at boundary, never inside

2 **Boundary Behavior**

Extremes happen on the domain's edge

3 **Applications**

Proves uniqueness and stability results

> Intuitively, analytic functions "spread out" their values—they can't concentrate maximum magnitude in the interior like some real functions can.
